Sheet 3

Exercise D

O Under the joint distribution X, Y,~ p(x,y)

L(Y, f(x)) is a r.v. Since L is bounded

(and we'll assume integrable since any sensible

choice of loss function is), L(Y, f(x)) = L

has a defined expectation, Eposy (L). Since

the draws yi, zi are iid, we have by UN

(more precisely, the strong law of large numbers)

1 Epixy (L)

substituting definitions,

Remp (f, D) as. Episy (L(Y, f(x))) = R(f).

As desired.

2) Suppose the distribution of training date does not match the true distribution that the training data is sampled from. This can happen very cessify for small 1DV.

The trainine data consists of a finite sampling from a trunction, (cleterministic or rendown) and so there are many interpolations which achieve the finite data set, but do not match the true function (they can't all metch since there's only one true function).

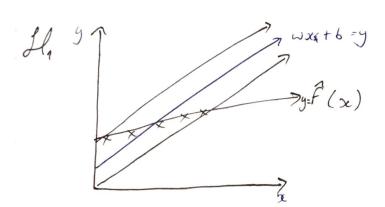

The bies - variance trade off states that for a data set Dr. fixed so, and trotantially ronelan) (about district

 $E((Y-\tilde{f}(x))^2) = Var \tilde{f}(x) + Bies(f(x))^2 + \sigma_e^2$

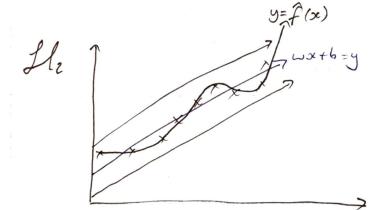

When he randomly draw D, Te^2 is the variance of the error, supposing an additive noise model Y = f(X) + E with $Var E = Te^2$. We call this the irreducible error, which provides a minimum error (at loost for this world error model and MSE loss).

This equation shows that it's not sufficient to minimise bies (which a very flexible model closs permits), since such models have high variance under rejected draws of D. On the other hand on insufficiently flexible model class will have low variance under draws of D., but (at lost on averge) will have high bics. Thus everly and underly-flexible model classes are to be arrival. The lessons generalise beyond MSE loss and adolitive arror.

(b) Blue = = wx; +6, Black = 95% error bor bounds x = data draws.

fachieves law empirical arror, but alsosnit match ideal fit — well: high R.

Kristing In

C) K-fold CV simulates K draws from D, allowing an estimate of Var DA(fm, V), allowing us access to another component within the bias-variance trade off.

(3) a) By the application of the toner law in the hint,

R(f) = [Fp(2) [Rf(2)] = [Ep(2) [II (f(k) + y | x=2e)]

No longer random

So tome minimise R(f), It suffices to minimise $1 (f(x) \neq y | x = x)$ for all choices of x. But we must have $f(x) \neq 21$ to achieve this minimality since $y \in 21$, and minimisation over p(x) = x = x excetly is achieved when the more probable y is chosen:

 $f(x) = \underset{k \in \{0,1\}}{\text{agmer}} p(y = k | x)$

which is exactly the MAP rule.

6) Optimal choice of P: we wish to minimize

R(f) = Epra) [R(fla)]

= Epiz) [Epizy 11y - f(x) 112 / x=2]

doose grap that minimises Il y- grap 1/2 over y-p(y) It is known that the minimiser of the a squared L2 norm is the mean. This chose

frap: & H(Y/X=x)

@a) Notice, as before that L=L(y, f(x)) is a r.v. depending on draws from y ~ p(y) and fox), &~ p(x). Since P(A) = E(L) and Pemp (f(D) = & & Li with Li= L(yi, f(xi)), we can apply Hoeffoling's bound since (for field) Let 1 = | Remp(FID) - R(FI), and d = \(\frac{m^2 \in (218)^7}{2N} \). Then Peh FRange Dexit26 Pr(A<&d) 7, 1-8. 6 S7.1-Pr(Axd) = Pr(A7.d) Now applying Hoeffoling's bound with E=d,

Now applying Hoeffoling's bound with $\varepsilon=d$, $Pr(17:d) \leq 2\exp(-\frac{2N}{m^2}d^2)$ $= 2\exp(-\frac{2N}{m^2}\frac{m^2 \ln \frac{2}{\delta}}{2N})$ $= 2\exp(-\ln \frac{2}{\delta}) = 2\exp(\ln \frac{\delta}{2})$ = 8

So $Pr(47, \sqrt{\frac{n^2 \ln (2/8)^2}{2N}}) \leq S$ $\Rightarrow Pr(4 - \sqrt{\frac{n^2 \ln (2/8)^2}{2N}}) \neq 1 - S, \text{ as obsided.}$

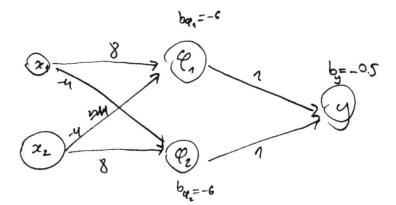

4

5

15) We wont $\Delta \approx D$ and we have finite N. The bound goes as fath fath, so increasing by a fector c the number of samples decreases the (probabilistic) bound by fatharpoonup D. On the other hand, the bound goes with M, so it's much moreon (quadratically in fect) of fathar if one can reduce the loss bound, rather than the number of samples.

We can also write $\sqrt{\frac{M^2 \ln(\frac{2}{5})^7}{2N}}$ as $\approx 1.92 \frac{M}{\sqrt{2N^7}}$ when 8 = 0.05 (in when the bound holds 95% of the fine). A factor of only ~ 2 isn't so bod, and it means that the M (which isn't much water our control) is at can be the main factor.

Exercise 2

(I'm not sure where the Sieses should be drawn, as it sounds like they're also supposed to have arrows, but the usual drawing of of a network doesn't easily permit that. In, is are alread in Circles even though no activation is applied to them.)

7
